Abstract (en)

[origin: WO9848590A1] The invention relates to subscriber information transfer in a local line distribution network (AN) using as information transport framework divided into equal sized time slots. At least some of these time slots are useful channel time slots, each of which is occupied either by transfer system data (ISDN) or by packet data (PS), and all useful channel time slots not occupied by transfer system data (ISDN) are combined in a remaining packet data transport channel. A protocol discriminator (PD) is incorporated into each time slot of the remaining packet data transport channel, thus enabling a univocal allocation of the data contained in a time slot of the remaining packet data transport channel to a traffic type.
