Abstract (en)

The method involves secluded handling of blood samples. The device for performing the method comprises a container adapted to contain a blood sample and a so-called phase body (4) inserted into the container beforehand, which after centrifugal treatment of the container separates the phases of the blood from each other. The container consists of a tube length (1) each end of which is closed by one pierceable, self-sealing closure (2 and 3 resp.). The blood sample is introduced by means of e.g. a cannula (5) through the one closure (2) and one of the blood phases formed during centrifugation is removed through the other closure (3) by means of e.g. a cannula.
