Abstract (en)

[origin: EP0033658A1] During the construction of an in situ cast concrete beam in a slot cut in a building wall, the wall (28) above is temporarily supported from the wall (17) below by a stool (11). The stool consists of a top plate (12), a bottom plate (13), and an intervening body comprising an upper plate (14), a lower plate (16), and a leg (15). The body and plate (12) are lifted, so as to tighten any looseness in the wall (28) above by hydraulic jacks (29). Packing is then inserted between the lower plate (16) and bottom plate (13) and the jacks (29) are removed before a beam is cast incorporating the stools. In this way only inexpensive parts are sacrificed within the beam and the jacks, and possibly containment (19) for the packing are recovered and reuseable.
