Abstract (en)
[origin: EP0054407A1] There is disclosed a device to protect against failure of a switch S and to give an alarm that the switch has failed. It comprises a circuit in parallel with the switch and containing a transistor T2 and diode D1 to cause such voltage drop in the circuit as to prevent current flowing through a second diode D2 when the switch S is closed. If the switch fails open, the potential at B will drop, and diode D2 will allow current to flow to the load L through the circuit. The current flow produces a potential difference across diode D1 to turn on another transistor T1 to cause an alarm to be given. The device may be used to test such switches without affecting the load controlled by the switch.
