Abstract (en)

[origin: EP0066305A1] 1. A process of producing an agent in the form of wire for treating molten material for making nodular iron, from a powder mixture which is sheath with ferrous metal and contains at least one of the metals (A) magnesium, calcium and rare earth elements, and at least one of the metals (B) iron, nickel and manganese, characterized in that the metal powder (A) is initially mixed with graphite powder or pearlite powder to form a reaction-retarding coating and is subsequently combined with component (B) and with a reaction-inhibiting component (C) of swellable silicates and/or coke and/or graphite to form the final mixture, wherein the metal powders (A, B) and component (C) have particle sizes between 0.02 and 2.0 mm and the powder mixture is composed of 30 to 80 wt. % (A), 10 to 60 wt. % (B) and 1 to 15 wt. % (C), the quantity of the coating being included in the quantity of component (C).
