Abstract (en)

An electrical circuit arrangement including a plurality of bistate devices such as vibration detection devices (2 to 7) connected therein, each occupying a particular position in the circuit, and each having a resistor (R2 to R7) associated therewith, such that a predetermined value of resistance normally prevails and the value is changed when any device changes state, comparison means (13 to 17) for comparing a parameter such as the current in the circuit with a reference parameter to indicate the identity of any device which has changed state and the position in the circuit of any changed-state device. In a second embodiment the bistate devices (2 to 6; 30 to 34) and resistors (R1 to R6) are connected in a multiterminal network (1, 1 min ; 35, 36) and connected to monitoring means (39) such as a microprocessor via a switching unit (40), the monitoring means (39) being operable in a plurality of different modes to monitor the devices (2 to 6; 30 to 34) across different combinations of pairs of terminals (1, 1 min ; 35, 36) such as to identify the position of any changed-state device in the circuit and to identify any failed or faulty device and to allow the circuit to continue to operate despite any failed or faulty device.
