Abstract (en)
[origin: EP0082326A2] 1. Coiling device consisting of a driven winding mandrel which is surrounded by an expandable drum for the reeling of strip-shaped material, which drum is subdivided into segments and the surface of which in the region of the strip end at the drum side displays an eccentric course gradually passing from inside into the normal circular shape and in which a step, which lies in a radial plane and extends in axial direction, of a height about corresponding to the thickness of the strip is formed at the transition between the surface regions of different radius, characterised thereby, that the step (16) is formed directly between the mutually facing longitudinal edges (14, 15) of two neighbouring segments (8', 8'') rigidly supported against the splaying device (9) and is settable or alignable (20) to the strip end at the drum side in dependence on the strip intake (22) during the starting-up of the winding operation by the winding mandrel drive (28).
