Abstract (en)

The standart Ballasts and starters used for the fluoresent lamps are based on the voltage kicks of a dying magnetic field in iron core. This is a somewhat artificial way of obtaining the voltage gradient necessary to establish an arc in the long vacuum tube. To facilitate this arc a cathode heating has been added for electron emission and arc starting. In the new design: 1- Instead of a weak voltage increase a dependable high voltage level is created by the sound autotransformer principle. 2- Instead of having the fully rated voltage primary coil, a much shorter one is subjected to the rated voltage for a few seconds and also protected from damage by a carefully chosen PTC (Positif Temperature Coefficient Thermistor) to separate the primary from the rated voltage circuit. 3- Therefore, with the aid of the PTC, from a 1 : 2 ratio autotransforme a voltage of 3 x V (rated) is obtained instantly. 4- This very short durated voltage is enough to strike an arc even for a very low (140 V) network and light a lamp without a starter. 5- This high voltage is harmless since it has the secondary coil in series as a ballast in the lamp circuit.
