Abstract (en)

[origin: EP0104337A2] In a device for feeding single sheets (24) stored stacked in a magazine (22) to the platen (10) of an office machine, the separation roller (32) drawing the sheets out of the magazine and transport rollers (36, 38) conveying the sheets to the platen are driven via a gear by the platen (10). The drive is effected in positive engagement via a rotating drive control element. The latter has a toothed circumferential portion (56) which can only come into engagement with the separation roller (32) when a sheet is to be drawn out of the magazine in each case. The transport rollers (36, 38) are driven by a toothing (60) of the drive control element which has a gap (62) which interrupts the drive during the period in which the sheet fed by the separation roller (32) arrives at the transport rollers (36, 38). The transport rollers (36, 38) are retained by a locking device during the interruption of the drive. A precise starting position for the line positioning of the sheet is obtained with little outlay on design and control. <IMAGE>
