Abstract (en)

[origin: US4604621A] The electromagnetic transmission in an interference-laden environment of events defined by the time of their occurrence is accomplished by repeatedly generating, at equal intervals after occurrence of the event, signals representing the occurrence of the event. An event which must be defined by the time t_e at which it occurs triggers a switch which in turn triggers a time base whose signal is sent to a counter. The counter produces at its output a sequence of pulses which are coded in a coder. The code indicates for each pulse the deviation in time ΔT_i which separates it from the time at which the event occurred. The sequence of pulses is sent electromagnetically to a receiver via a transmitter. The first interference-free pulse received is processed by a decoder which provides the value ΔT_i to an arithmetic unit. The arithmetic unit subtracts the value ΔT_i from the time of day t_h to obtain the time of day t_e of the event. The device is applicable in particular to the timing of sporting events.
