Abstract (en)

[origin: EP0136544A2] 1. A device for reducing the braking torque of internal combustion engines in motor vehicles in the change from pulling to overrun operation, the device having a power-regulating element the return of which in the direction of its rest position is influenceable by a damper (7) which is effective when a drive connection exists between the internal combustion engine (1) and the driven wheels of the motor vehicle, characterized in that the damper (7) is so formed that, throughout the displacement of the power-regulating element (2) in the direction of its rest position, it is continuously effective in the direction of a reduction of the speed of the displacement movement of the power-regulating element compared with the case of operation without the damper being effective, and that the damper is ineffective when there is no drive connection between the internal combustion engine and the driven wheels of the motor vehicle.
