Abstract (en)
[origin: EP0153498A2] In the door-locking system there is a small transmitter which can be transported and actuated by the driver and which emits electromagnetic radiation. In the motor vehicle there is at least one receiver which receives the electromagnetic radiation and which triggers the actuation of the door lock. The small transmitter comprises a memory (diode matrix 3) for a code and a modulator (encoder 1, flank modulator 9, transmission stage 16) for modulating the electromagnetic radiation by means of the code. In the receiver there are a reception part receiving the modulated radiation, a demodulator (monostable multivibrator 20, D-flip-flop 21) and a comparator (28) comparing the demodulated code with a code stored in a code memory. An actuator (31) for the lock is connected operatively to the comparator. The transmitter contains the modulator for modulating the radiation with a pulse-code/pulse-position modulation (PCM/PPM). Corresponding to this in the receiver is a demodulator for demodulating the PCM/PPM-modulated radiation. <IMAGE>
