Abstract (en)

A method and circuit for processing pulses in pulse pile-up situations, wherein each pulse is sampled with a second frequency which is a subfrequency of a first frequency. The start time of sampling is measured dependent on the first and second frequencies. Also the number of samples is stored. Furthermore, the start time of a pile-up pulse is measured dependent on the first and second frequencies. Finally, each pulse to be processed preceding a pile-up pulse is corrected by adding remaining tail samples dependent on the start time of sampling, the stored number of samples of the pulse until the last sample prior to the occurrence of a pile-up pulse and the stored number of samples of a previously sampled pulse and each pile-up pulse is corrected by subtracting the tail samples added to the preceding pulse dependent on the measured start time of the pile-up pulse, the number of samples of the pile-up pulse and the number of samples of the preceding pulse prior to the starting time of the pile-up pulse.
