Abstract (en)

[origin: EP0171245A2] An A.C. motor 4, for example driving a fan 5, can be switched to low speed or high speed operation, for example by pole change switching or by switching the motor supply frequency. To prevent overheating of the motor and conserve energy, a switching operating circuit effects the switching automatically in response to the output of the motor. To prevent unwanted switching, operation of the switching means is restricted for example by time delays, or by setting different thresholds for switching from high to low, and from low to high speed operation respectively. Switching from low to high speed operation may also be inhibited by a temperature detector if the motor is tending to overheat. <?? >Switching and control circuits of various kinds are described.
