Abstract (en)

[origin: EP0211366A2] A mobile radio set exhibits a main memory (20) in which all transmitters which can be received in the possible action radius of the radio set are stored, a transmitter identification device (19) for identifying the receive transmitter and for determining receivable alternative transmitters with the same transmitted programme and a device (22) for testing the quality of reception which continuously selects the transmitter having the best quality of reception at the reception site from among the alternative transmitters and the received transmitter. For reliably testing the quality of reception with only one existing receiver train, the test device (22) is used for sampling the quality of reception of the currently received transmitter and in extremely short mute times the quality of reception of the alternative transmitters, and the samples are averaged and stored in a memory (32, 33). A comparison circuit (34) selects the transmitter having the best quality of reception by means of the comparison of the current samples and of the mean values.
