Abstract (en)

[origin: WO8703720A1] Process for determining the operating states of a vehicle from the output signals of a sensor for a relevant operating quantity in which, by means of an output signal from the sensor and further analysers an analysis is first made of a sensor signal relating to different relevant operating parameters and, on the basis of the value of the operating parameters an n- (for example two-) dimensional specimen is produced. This specimen, which in principle is known also from the field of speech recognition or processing, is compared with pre-set specimens and enables a simple and rapid analysis of the current operating state or rapid recognition of an impending critical operating state. Corresponding warning and remedial action are then carried out without delay.
