Abstract (en)  
[origin: EP0238851A2] Methods are described for assaying human and mammalian immune system function. Methods for determining the reserve capacity of a subject's immune system to provide amplifier and suppressor responses are described, together with methods for titrating dosage amounts of agents modifying immune response. In the preferred embodiments, IL-2 or G-IFN production are used to measure positive (i.e., amplifier) immune capacity or reserve, and cell proliferation is used to measure negative (i.e., suppressor) immune capacity or reserve.  
[origin: EP0238851A2] A method of assaying an immune system response of a human or mammalian test subject comprises (a) prepg. a peripheral blood lymphocyte (PBL) population from a blood sample taken from the subject, (b) exposing at least a portion of the population to of an amplifier (I) and an agent (II) for activating an immune system response and (c) assaying the prodn. in the population of a material (III) that is an index of immune system response induced by (II), so that an immune system assay result is provided that is representative of the amt. of the subjects' immune response to (II). Pref. (II) is PHA, pokeweed, ConA or tetanus toxoid. (I) may be e.g. Amplifier Beta, Amplifier Zeta-1, Amplifier Eta, Ta or TGG. Pref. (III) is IL-Z or gamma-interferon and the prodn. is assayed by measuring labelled thymidine incorporation.
