Abstract (en)
According to the invention, the pneumatic device for presses includes two cylinders (1,2; 31, 32) with different diameters, communicating with each other, within which slide two pistons equipped with shafts (7,9; 33, 34) integrally connected with one another. The piston (1; 31) transmits a negligible power and it only serves the purpose of moving the upper part of the die until it brings it in the vicinity of its shutting point, while the other piston (2; 32) transmits the maximum power of the press in correspondence with the end stretch of the piston stroke. The device presents accident-prevention characteristics, since the entire stroke previous to the shutting of the die is performed by the cylinder transmitting a reduced power. A variation of execution of the device foresees that the lowering cylinder (31) and the power cylinder (32) be arranged side by side and with their axes parallel with each other.
