Abstract (en)

[origin: EP0282956A2] The container pump has a sliding sleeve (13) at the bottom end of its housing shell (5), which in the open position frees the inlet apertures (11) at the bottom end of the housing shell (5) and in the closed position, in which it is applied against a base plate (12), closes these inlet apertures. The base plate (12) projects in a radial direction beyond the housing shell (5), thereby sealing the pump off from below. Fluid can thereby be admitted only via the inlet apertures provided on the circumference of the pump's housing shell (5). Displacement of the sliding sleeve (13) is achieved by the provision of thrust pieces (19) on the underside of the sliding sleeve, which in the closed position project downwards beyond the base plate (12) and when the pump is switched on are forced upward against the action of a spring (15) loading the sliding sleeve (13) owing to the downward acting weight of the pump, as a result of which the sliding sleeve (13) is released from its sealing seat on the base plate (12) thereby permitting the entrance of fluid through the inlet apertures (11). When the pump lifts, the sliding sleeve (13) is forced back into its closed position by the spring (15). The sliding sleeve can also be operated manually by an operating device. <IMAGE>
