Abstract (en)

[origin: EP0286807A2] A method for regulating access by concurrent transactions to hierarchically-related resources distributed about a loosely-coupled multiprocessor system is disclosed. Lock requests are first decided by a local lock manager (2a...2n) and then by a central lock manager (1). When a single local lock manager (2a...2n) holds locks on a resource, that local lock manager has sole interest in the resource. While a lock manager has sole interest in a resource, it can acquire locks subsidiary to the resource without consulting with the central lock manager (1). Sole interests of objects are shifted dynamically for optimising local control of objects, thereby minimising communication and transaction wait time.
