Abstract (en)

In this device of the type described in the main patent, the means bringing the arms from their inactive position into their active position consist, on the one hand, of a control rocker (52) which, capable of pivoting between two positions, front and rear, respectively, about a horizontal transverse shaft (53) arranged in front of the shaft (9) of the flap, is integral with an elastic thrust device (60) whose notched free end (67) is capable, when the rocker (52) is brought into a rear position, of capping a transverse nose element (68) projecting from the front end of the flap (3) and of pivoting this flap in the direction of lift of the arms (2) relative to a wedging cradle (69) on the ski, and, on the other hand, of spring means (54) for spacing the arms in the active position. <IMAGE>
