Abstract (en)
An improved method for storing at least two substances (6, 7) in complete independence from each other until use when they are required to be mixed utilising a compartmented vial (1) which comprises two compartments (A, B) connected by a constricted neck, in which is positioned a plug (2), and an ordinary rubber stopper (3) positioned in the mouth opening (C) of the vial. In use, a syringe needle (8) is pushed through the rubber stopper and air is injected into the upper compartment, thus causing a rise in pressure in the upper compartment forcing the plug to be displaced out of the neck and allowing the two compartments to communicate and their contents to combine to form a mixture, with which to charge the syringe body (9).
