Abstract (en)  
[origin: WO8805582A1] An apparatus for the prevention of disasters in which a plurality of terminal devices are connected to a receiver which collects data by polling from the terminal devices. Specific data such as the data inherent in the kinds of the terminals are automatically registered in the receiver at the time of initial setting, and there is no need of transmitting specific data from the terminal device to the receiver for each polling. For this purpose, the receiver is provided with first means that collects and stores specific data related to the terminal devices. When a plurality of receivers are arranged in a hierarchical manner, the receiver of the lowest rank is provided with the above first means. Further, each of the receivers includes second means for collecting specific data of terminal devices from a receiver of a lower rank and transferring the collected data to a receiver of a higher rank, and third means for storing the specific data on the terminal device received through the second means from the receiver of the lower rank.
