Abstract (en)

[origin: EP0322516A2] In a solid bowl centrifuge, in particular for separating media with different density or their mixtures and/or suspensions, which are difficult to separate into a comparatively lighter and at least one heavier phase, having a drum which is rotatably mounted on a shaft and forms in itself a settling basin, and having elements for feeding in the media to be separated and for discharging the separated phases, it is proposed that the discharge element (8) for the lighter phase (14) be led to an overflow (8a) on a drum end wall (16) and the discharge element (9) for the heavier phase (13) be constructed, starting from the lowest region (17) of the settling basin (3), with a conveying device (18) and be arranged so as to open into the discharge-side part of the hollow shaft (43b) of the expulsion body (6). In this arrangement, the conveying device (18) can be constructed as a compressed-air liquid siphon (37). <IMAGE>
