Abstract (en)

An antialias filtering and subsampling system incorporates a compound accumulator including three cascade connected accumulator circuits (52,53,54) conditioned to integrate and dump the integrated values of n input samples. The integrated values from the three integrators are scaled, delayed and combined to produce subsampled values of a signal which has been filtered according to the transfer function $[\sin(n \pi fT)/n \sin(\pi fT)]^{<3>}$, where T is the period of the sampling frequency. This function can be generated by a piecewise linear combination of samples derived from accumulators each comprising, according to an aspect of the invention, a plurality of parallel or cascaded adder circuits (520-525) which, responsive to the input samples, provide their outputs at respective sum data terminals (SDO) which are successively coupled (P1...P6) to a serial output port (70).
