Abstract (en)
[origin: EP0341505A2] In order to induce ultrasonic oscillations in a liquid contained in a container, ultrasonic oscillators are bonded onto the outside of a wall serving as a diaphragm. Due to cavitation erosion, the seal on this wall is broken, which leads to the destruction of the entire device. In order to prevent this, it is proposed to attach a retaining ring near to the oscillation node on the ultrasonic oscillator, which then permits insertion into the container so that the ultrasonic oscillator acts with its sound-radiating cone directly on the liquid. <IMAGE>
