Abstract (en)
[origin: EP0343719A2] A simple and space-saving circuit arrangement for forming an output signal as a linear combination of a number of input signals (S_1, \dots, S_n) is described. This contains only one current control element (11, ..., or $1n$, respectively) for each input signal (S_1, \dots, S_n respectively), particularly a transistor. The transistors are connected at one end with taps (41, ... or $4n$ respectively) of a chain of feedback resistors (R_1, \dots, R_{n-1}) and, at the other end, alternately to a first (31) and a second (32) output connection. The parallel connection of the feedback resistors (R_1, \dots, R_{n-1}) directly following the tap (41, ... or $4n$, respectively) for the current control element (11, ..., or $1n$, respectively) is dimensioned in accordance with the factor by which the input signal (S_1, \dots, S_n respectively) is weighted in the linear combination. <IMAGE>
