Abstract (en)

A procedure transforms a level of a universal data stream not supported or required by an application into a level that is supported or required by the application. The function, parameters and options of a universal data stream are described, and this information is used in conjunction with application supplied information to determine which of available function, parameters and options, based on the application running, the task requested and the capabilities of the system are to be used during system interpretation and transformation of the data stream. More accurate interpretation and transformation of the data stream is provided insuring that data loss and function misinterpretation are minimized. Operator flexibility is improved because depending on the function level supported, the system can decide to transform a function to a more manageable representation. Further, the interchange data stream can be optimized enhancing overall system useability.
