Abstract (en)
The button is foreseen with a head (1) on a stem (2) kept in issue by its annular end (3) with outer bending, within the mouth-piece (4) of a central emerging part (5) of a layer (6). The above free articulation allows the head (1) slanting and to change its distance from the tissue, which facilitates the eyelet practicability. The button can be fitted on the tissue by means of a small ring (7) with jaws (8) which penetrate into the same tissue without impairing the fibres and, after squashing, are set to block the whole into a hollow (9) formed by the outer part of the layer (6). The means allows to reduce encumbrance, a planning versatility, a shape reentering in employ condition, and the possible use of valuable materials even of small diameter and thickness on the stem end.
