Abstract (en)

[origin: EP0358132A2] The invention relates to a holding device (1) for the anchorage of a membrane (2) to a stationary structural member (3). The holding device (1) has a holding piece (4) which is in the form of a clamping means and has two opposed clamping surfaces (7, 8), between which the edge (5) of the membrane (2) is firmly clamped. For this purpose, a clamping force production means (9) is provided which acts, outside the clamping surfaces (7, 8), upon a force-introducing part (10) connected to the clamping surfaces (7, 8). As a result, on the one hand it is achieved that tangential forces are safely taken up by the application of clamping forces to the edge of the membrane, and on the other hand it is not necessary for this purpose to provide the membrane (2) for example with a perforation for the passage of the clamping force production means, which has led to a considerable material weakening in the case of holding devices known hitherto. <IMAGE>
