Abstract (en)

[origin: EP0362141A2] Electrically conductive networks of crystal needles are formed on a substrate by optionally substituted tetrathio-, tetraseleno- or tetratelluronaphthalenes or -tetracenes with electron acceptors, especially with halogen-containing organic compounds. Said needle networks can be coated electrolytically with metals, and/or be delaminated from the substrate with polymers in the form of films which are electrically conductive on one side.
