Abstract (en)
[origin: EP0368724A1] The distribution head comprises a central channel (5), of which a section integral with the end (13) of the head is formed by a cylindrical wall (7) which stops at a certain distance (d) from a bottom wall (12), and a tube (14) mounted slideably relative to this central channel section (7). Towards its end intended to be turned towards the container, the tube (14) comprises openings (15) in its wall. In a storage position, the tube (14) interacts only a minimum amount with the said section (7) and the openings (15) do not communicate with an annular chamber (6) containing the additive (2), whereas in a second working position, the tube has been displaced by sliding and the said openings (15) establish communication between the central channel (5) and the annular chamber (6). <IMAGE>
