Abstract (en)

[origin: US5014870A] A container is disclosed which makes the coupling a coupling device of lifting gear, such as a crane, with the container without requiring additional alignment operations as performed by special instrumentalities or by manual labor. The coupling device includes a first coupling member which consists of a bushing having an upper flange-like border, which is arranged centrally on the top side of the container. This bushing serves simultaneously as a guide member for a second coupling member which is in the form of a pull bar. The second coupling member, as well, is provided with an upper flange-like border. When handling the container one may use the coupling device with at least two hooks, which are fitted, respectively, under the flange-like borders of the coupling members in a circumferential distribution.
