Abstract (en)
[origin: WO8909114A1] The eccentric drive of an eccentric grinding machine is designed to eliminate the undesirable effects due to operation of the grinding disc and to improve the cooling. To permit decoupling of the eccentric drive from the grinding disk (24), only the central region of the latter is connected to the intermediate disk (17), which is provided with a gear rim (21, 22). At the same time, the intermediate disk (17) conducts the heat generated in the bearings (10, 11) to the suction air stream flowing through the ventilation ports (28, 29). The eccentric grinding wheel executes four different fine grinding movements and is therefore suitable for all grinding operations.
