Abstract (en)
[origin: EP0406532A1] What is described is a process for controlling the starting of a loom (1) equipped with an electromotive main drive, the stoppage time, the cause of the stoppage and the type of weave being processed in the machine at the time of stoppage being determined by the machine control (2). These parameters are processed via a microprocessor (4) which accordingly selects from a library (8) a suitable program for running up the machine, via which the run-up of the machine is then controlled. By means of the process according to the invention, inadequacies of previously known processes, in which adverse variations in the properties of the yarns occurred during the stoppage of the machine, can be avoided, for example after a preset stoppage time. <IMAGE>
