Abstract (en)
[origin: EP0430059A1] A device for supporting loads (1) has at least one connecting element (5), which can be taken up by at least one load. In a region facing away from the connecting element, it is provided with a support (2) which can be taken up by a guide (18). At least one coupling (3) is arranged between the support and the connecting element. The coupling is designed as a joint with at least one degree of freedom. The joint is designed as a rotational joint which permits rotary movements of the connecting element for the purpose of support. It has a bearing sleeve (10) which partially surrounds a joint head. Towards the connecting element, the bearing sleeve has a joint opening which, starting from an interior space of the joint, widens towards the connecting element. The joint has play which permits displacement of the joint head in the direction of a shank longitudinal axis. The support is designed as a support head which can be accommodated by an insertion opening of the guide.
