Abstract (en)

[origin: EP0434603A1] The device (1) consists of a retaining element (2) having triangular recesses (5) into which a crossbar (3) is placed. The upper region (6) above the recess (5) is bent, in a first step, to such an extent that the crossbar (3) is unable to slip out of the recess (5), but can be displaced to-and-fro in the recesses as far as the two covering caps at the ends of the crossbar (3). To lock the crossbar (3) in the retaining element (2) the upper region (6) in the retaining element (2) can be bent by a lever (11) inserted into the hole (7), so that the crossbar is clamped in the recesses (5). The retaining element (2), bevelled to a point (4) at the bottom, is produced from an angle iron and the crossbar is produced from an angle iron or from a reinforcing bar. The device is inexpensive and requires no additional loose elements or tools for use.
