Abstract (en)
[origin: EP0457347A2] The semiconductor memory device according to this invention includes data bus lines each comprising one single wire line, a means for inverting the level of the data bus line, a capacity element which is connected at one end with the inverting means and at the other end with the power source and has a capacity substantially similar to the parasitic capacity of the data bus line, and a transfer gate which receives control signals at a control terminal thereof connected between an end of the capacity element and the data bus line. By structuring the device as above, data could be read out or written in by the data bus line provided in a number of one-to-one relation with one bit of input/output data to thereby reduce the area of the regions where data bus lines should be placed without impairing the operational speed. <IMAGE>
