Abstract (en)

[origin: EP0461093A1] A method of improving the amplitude-frequency characteristic when receiving a target echo (M) in a radar system installed on a satellite or an aircraft and carried at a given height (h) above the earth's surface. The method utilizes the known method of compressing a received pulse which contains a number of frequencies (f1-f2) in order to obtain improved dissolution of the target. According to the method, the receiving lobe of the radar is swept, independently of frequency, over a given larger angular area ( THETA b - THETA a) within which the target (M) is located. Within the smaller angular area ( DELTA THETA ) occupied by the target as seen from the radar, i.e. the momentary width ( DELTA w ) of the target echo, however, the receiving lobe is controlled in dependence on the frequencies (f1-f2) so as to obtain a number of optimally located receiving lobes for the smaller angular area ( DELTA THETA ).
