Abstract (en)

[origin: EP0467074A2] In a process for making a brick which has a holding aid in the form of a recess on at least one side, raw material is extruded in an extrusion operation through an opening of a die and is formed into a continuous body. The recess, serving as a holding aid, in the continuous body is formed by the continuous body being extruded with an intermittently varied contour. A corresponding apparatus has a die with an opening through which raw material can be extruded and formed into a continuous body. An apparatus for forming the recess comprises a device for changing the cross-section of the opening of the die, in which arrangement at least one blade-like diaphragm can be moved for changing the cross-section through which the continuous body is extruded and can be made to overlap the latter. With the apparatus, instead of producing a holding aid, the motion of the continuous column can also be regulated so as to be of limited duration. <IMAGE>
