Abstract (en)
[origin: EP0475219A1] In a passive infrared intrusion detector, which evaluates the body radiation of an intruder with the aid of a dual sensor (3) having two sensor elements (8, 9) in a differential circuit in order to give an alarm signal, an attempt to put the detector out of action by covering or spraying the radiation entry window (2) is detected and signalled by a monitoring beam path from an infrared radiation source (7) through the window (2) via a further optical system (6) to the sensor (3). In order to achieve a different irradiation of the two sensor elements (8, 9), this optical system (6) generates at the site of the sensor (3) irradiation having an intensity which decreases gradually to the sides. If the sensor elements (8, 9) are located laterally offset on the decreasing edges of the irradiation curve, their irradiation differs without the need for a precise adjustment. This can be achieved, for example, by forming aspherical mirrors, or as segmented mirrors (6.1, 6.2, ..., 6.5), which form at the sensor site overlapping irradiation spots (B1, B2, ..., B5) which overall have a stepped intensity curve. If the step width is not larger than the spacing (ds) of the sensor elements (8, 9), the two sensor elements (8, 9) necessarily receive a different irradiation. <IMAGE>
