Abstract (en)
[origin: EP0506357A2] Polarized light is input to an optical modulator (16) typically consisting of an electrooptic crystal. The polarization state of the input light is changed in accordance with a voltage applied to the optical modulator (16). Receiving the light output from the optical modulator, a polarization interferometer (18) produces an interference fringe on the input surface of a photodetector (20) such as a streak camera or a CCD line sensor (134). Based on an output signal of the photodetector (20), an analyzing device (22) calculates the pitch and a movement distance of the interference fringe to determine the voltage applied to the optical modulator (16). <IMAGE>
