Abstract (en)

[origin: WO9112035A1] A method and a device for matching the blood flow rate in a heart prosthesis driven by an electrical actuator (18) with the available flow in the patient's venous return. A device comprises a sensor (11) for measuring a physical operational parameter of the prosthesis, of which the pass-band extends beyond the variation frequency of the blood flow, and includes a device (10) for determining the position of the prosthesis, a central processor (15) receiving signals from the sensor (11) and the device (10) and controlling a supply means (5) of the actuator, and a memory (16) for storing the normal values of the physical operational parameter of the prosthesis. The device is designed in particular for monitoring the operation of human heart prostheses.
