Abstract (en)

[origin: EP0535549A2] A device for inductively transmitting control information to railway vehicles is disclosed, in which device in each case track conductor arrangements with two track conductor loops (S1, S2) are laid at individual transmission sites. The track conductor loops are operated independently of one another. Each of the loops transmits an identification code in addition to the control information. The order of the identification codes in a conductor track loop arrangement is permanently assigned to a direction of travel (FR) and known to the vehicle. At the vehicle, only such control information is evaluated in which the sequence of loop identification codes in the received information corresponds to the vehicle's own direction of travel determined for example from the rotation of the wheels. <IMAGE>
