Abstract (en)
[origin: WO9303251A1] A motor-driven turnstile for providing cyclic access to a passage (16) to which a monitoring system or the like is allocated is controlled in such a way that, after a satisfactory monitoring result, each barrier arm (4) is first taken from the blocking position to a position at a small angle (alpha) to a subsequent holding position in which, after external pressure applied by the user, the arm is once again driven by the drive motor (6) and turned further until the next arm is in the blocking position.
