Abstract (en)

A multi-mode analog to digital converter (10) is described for converting an analog input into a digital value according to a linear or a companding transfer function. The converter (10) comprises a comparator (32), a successive approximation register (14) and a charge redistribution device (12). The comparator (32) compares the input voltage and a generated voltage. The successive approximation register (14) generates a provisional binary word responsive to the output of the comparator (32). The charge redistribution device (12) generates the generated voltage according to the provisional binary word and to a selected transfer function. The transfer function may be selected from the group consisting of linear and companding. <IMAGE>
