Abstract (en)
[origin: EP0581179A2] The invention relates to a device for correcting the cutting register in a rotary printing machine, in which a plurality of webs are printed and passed on to a folder connected to the printing units via a mechanical drive for common processing. In order to ensure that any changes arising from the folder and acting equally on the cutting register of all the printed webs can be compensated during the machine run with simple technical means requiring little adjustment effort, a correction member is inserted in the drive in addition to the folder, which correction member can adjust the angular position between the input drive and the output drive infinitely variably during the machine run and carries out a common total cutting correction of all the webs entering the folder. <IMAGE>
