Abstract (en)  
A liquid dispensing system, primarily for beverage, has an array of containers 1 from which liquid is to be dispensed simultaneously by gas under pressure in the headspace of those containers. Liquid is dispensed from each container through an isolating valve 5 and a common delivery tube 8 to a dispensing tap 9. Each valve 5 includes a float which responds to density of fluid therein and when sensing liquid provides communication between its container 1 and the tap 9 and when sensing gas or foam therein from its container closes communication between its container and the tap 9. Alternative forms of isolating valves 5 may be used that are responsive to variations in electrical conductivity of fluid flow or variations in light absorption or refraction of fluid flow. <IMAGE>
