Abstract (en)
[origin: EP0593803A1] For positioning loads, a supporting element (11), which is resistant to bending in two planes and can be assembled from individual elements (1, 2), is formed during the positioning operation, so that both tensile and compressive forces can be transferred to the load to be positioned. After the end of work, there is a possibility of dismantling the support element into its individual components again in a space-saving manner by moving the device back into its starting position so that the support element can be accommodated, so as to be ready for use at any time, inside the range of movement of the loads to be positioned. <IMAGE>
