Abstract (en)

[origin: EP0603841A1] In a process for the winding of round material (8), a pressing device (4, 5) bearing laterally on the material is displaced so as to follow the winding operation, in such a way that the wound layers lie laterally close against one another. At the end of one layer, a distance corresponding to 1.5 times the material diameter is maintained between the pressing device (4, 5) and the bobbin flange, until the material has reached the next higher layer and lies in the turn groove between the last and penultimate turn of the previous layer. A suitable device has an axially displaceable pressing roller (5) and a winding bobbin (3) axially displaceable independently of the latter. The process and the device are especially suitable for thick round material which is difficult to bend. <IMAGE>
